Diffie-Hellman crucial exchange (D-H) is certainly a specific approach to exchanging cryptographic keys. Infrastructured network consists of a network with fixed and wired gateways. A cellular host communicates with a bridge in the network (called base station) within its conversation radius. This key can then be used to encrypt subsequent communications using a symmetric essential cipher. Wireless networks' is an emerging brand-new technology which will allow users to gain access to information and solutions electronically, no matter their geographic position. Cellular networks can be classified in two types:- infrastructured network and infrastructureless (ad-hoc) networks. It is one of the earliest practical types of important exchange implemented within the field of cryptography. The Diffie-Hellman key exchange technique allows two parties which have no prior understanding of each other to jointly set up a shared secret key over an insecure communications channel. The mobile device can move geographically although it is normally communicating. When it goes out of range of one foundation station, it links with new foundation station and starts interacting through it. In this approach the base stations are fixed. That is called handoff.
